UB Suppress (1.0:2/7/97) (UBSUPP)

SEGMENT DESCRIPTION

The UB Suppress 1.0 segment is designed primarily to suppress UB core background process launch on workstations that do not run UB. Core process launch is normally enabled by the installation of the GCCS COE aggregate segment (which includes UB Core).

The segment should be installed on any workstation where UB is NOT operational, as the absence of unneeded background UB processes will save network usage and a small amount of processing speed and will provide a significant reduction of socket usage on the TDBM Master. If UB is later installed on that machine, the segment will sense the change and will allow the core processes to be launched at next reboot.

The segment may be, but need not be, loaded on any workstation where UB is functional, as it will have no effect there (unless the UB segments are subsequently deinstalled, in which case the change will be sensed at next reboot).

INSTALLATION INSTRUCTIONS

Step 1: Verify installation of required segments:

GCCS COE 3.0.1.6.02G

Step 2: Install UB Suppress 1.0.

The following will be presented to the installer:

The user is prompted to reboot the system.

FIXES / NEW FEATURES

This release updates the following:

1. Created a segment that, at each workstation boot time, if the critical UB segments are *not* loaded (neither UBApps nor JMTK), will cause UB core processes (e.g., Tdbm) *not* to be launched in the background.
